

**REMARKS**

Amendments to the specification have been made and are submitted herewith in the attached Substitute Specification. A clean copy of the specification and a marked-up version showing the changes made are attached herewith. The claims and abstract have been amended in the attached Preliminary Amendment. All amendments have been made to place the application in proper U.S. format and to conform with proper grammatical and idiomatic English. None of the amendments herein are made for reasons related to patentability. No new matter has been added.

Attached hereto is a marked-up version of the changes made to the claims by the current amendment. The attached page is captioned "**Version with markings to show changes made**".

In the unlikely event that the transmittal letter is separated from this document and the Patent Office determines that an extension and/or other relief is required, applicant petitions for any required relief including extensions of time and authorizes the Commissioner to charge the cost of such petitions and/or other fees due in connection with the filing of this document to **Deposit Account No. 03-1952** referencing docket no. 449122026100. However, the Commissioner is not authorized to charge the cost of the issue fee to the Deposit Account.

Respectfully submitted,

**VERSION WITH MARKINGS TO SHOW CHANGES MADE**

For the convenience of the Examiner, the changes made are shown below with deleted text in strikethrough and added text in underline.

**In the Claims:****Patent claims What is claimed is:**

1. (Amended) A method for switching a connection between two subscribers (7,8) of a communication network with a common signaling channel (6) which is independent of the information channels (5, 5a, 5b) and with transit exchanges (3) ~~consisting of in each case~~ **having** at least one switching network (4) and associated line trunk groups(2), the switching ~~being effected~~ **occurring** after a request from outside ~~this~~ **of the** communication network, comprising: ~~the following steps~~

a)

connecting two inputs for transmission links at a transit exchange (3) by a data line (12) and ~~permanently~~ allocating at least one pair of information channels(5a, 5b);

b) ~~Transmitting~~ **transmitting** a control signal on the common signaling channel ~~such~~(6) ~~which has the following effect:~~

that a connection to the ~~a~~ first subscriber (7) **of the two subscribers** is switched through from ~~one information channel (5a)~~ **a first** of the information channels (5a, 5b) ~~in each case~~ ~~permanently~~ allocated to one another, and

that a connection is switched through to the ~~a~~ second subscriber (8) **of the two subscribers** from ~~the a second information channel (5b)~~ of the information channels (5a, 5b) ~~permanently~~ allocated to one another; **and**

c) ~~Forwarding the~~ **forwarding a** terminal signaling of the connection to the first subscriber ~~to~~ **of** the connection to the second subscriber via the common signaling channel(6) ~~and conversely,~~ **and forwarding a terminal signaling of the connection to the second subscriber of the connection to the first subscriber via the common signaling channel.**

2. (Amended) The method as claimed in claim 1, ~~characterized in that~~ wherein the signaling on the common signaling channel (6) is ~~effected~~ in accordance with the ITU-T signaling system No. 7.
3. (Amended) The method as claimed in claim 2, ~~characterized in that~~ wherein the signaling messages of ~~the~~ an ISDN User Part (ISUP) are transmitted from the first connection to the second connection and ~~conversely~~ from the second connection to the first connection via the ITU-T signaling system No. 7.
4. (Amended) The method as claimed in ~~one of claims 1 to 3~~, ~~characterized in that, as inputs, those for~~ claim 1, wherein PCM30 transmission links are used as inputs.
5. (Amended) The method as claimed in ~~one of claims 1 to 3~~, ~~characterized in that, as inputs, those for~~ claim 1, wherein PCM24 transmission links are used as inputs.
6. (Amended) The method as claimed in ~~one of claims 1 to 5~~, ~~characterized in that~~ claim 1, wherein the control signal is transmitted via an existing controller (21) of the transit exchange.
7. (Amended) The method as claimed in ~~one of the preceding claims~~, ~~characterized in that~~ claim 1, wherein a connection after a request from another communication network is initiated by a program installed on a network server (13) which is connected to ~~this~~ the other communication network.
8. (Amended) The method as claimed in claim 7, ~~characterized in that~~ wherein the other communication network is the Internet.
9. (Amended) A device in a transit exchange (3) for switching a connection between two subscribers (7, 8) of a communication network with a common signaling channel (6) which is independent of the information channels (5, 5a, 5b) and with transit exchanges (3) ~~consisting of~~ in each case having at least one switching network (4) and associated line trunk groups (17), the

switching being effected occurring after a request from outside of the communication network, comprising a):

at least one connection between two inputs for transmission links at the transit exchange by means of a data line (12) and permanent allocation of at least one pair of information channels(5a, 5b); and

b) ~~A~~ a controller (10) (~~CtD controller~~) which is connected to the common signaling channel (6) and which conducts on the common signaling channel (6) a control signal having the content that a connection is present on one information channel (5a) of the information channels (5a, 5b) in each case permanently allocated to one another, which connection ~~must be~~ is switched through to one subscriber (7), and that a first of the two subscribers, and a connection is present on the second information channel (5b) of the information channels (5a, 5b) permanently allocated to one another, which connection ~~must be~~ is switched through to the a second subscriber (8) of the two subscribers, and which forwards the terminal signaling of the connection to the first subscriber (7) to the connection to the second subscriber (8) ~~and conversely~~; and from the second subscriber to the first subscriber.

10. (Amended) The device as claimed in claim 9, characterized in that the controller (10) uses the signaling protocol according to the ITU-T signaling system No. 7.

11. (Amended) The device as claimed in claim 10, ~~characterized in that~~ wherein the controller (10) transmits the end-to-end signaling messages of the ISDN User Part (ISUP) from one connection to the other ~~one and conversely~~ connection.

12. (Amended) The device as claimed in ~~one of claims 9 to 11~~, ~~characterized in that~~ claim 9, wherein the inputs are those for PCM30 transmission links.

13. (Amended) The device as claimed in ~~one of claims 9 to 11~~, ~~characterized in that~~ claim 9, wherein the inputs are those for PCM24 transmission links.

14. (Amended) The device as claimed in ~~one of claims 9 to 13~~, characterized in that **claim 9, wherein** the controller (10) ~~(CTD controller)~~ is an existing controller of the transit exchange(3).
15. (Amended) The device as claimed in ~~one of claims 12 to 14~~, characterized in that **claim 12, wherein** the transit exchange (3) is a transit exchange (3) of the EWSD system and the inputs are connected by two accesses for PCM lines (22) in each case being connected at one line trunk group(2) ~~(LTG)~~.
16. (Amended) The device as claimed in claim 15, ~~characterized in that~~ **wherein** the controller (10) ~~(CTD controller)~~ ~~is the~~ **is a** group processor of the line trunk group(2).
17. (Amended) The device as claimed in ~~one of claims 9 to 16~~, characterized in that **claim 9, wherein** the controller (10) is connected to a network server (13) which, ~~in turn~~, is connected to another communication network ~~in order~~ to initiate the connection by a program on ~~this~~ **the** network server (13) after a request from the other communication network.
18. (Amended) The device as claimed in claim 17, ~~characterized in that~~ **wherein** the other communication network is the Internet.

**In the Abstract:**

Please replace the Abstract with the substitute Abstract attached hereto.

## Description

METHOD AND DEVICE FOR SWITCHING A CONNECTION IN A  
COMMUNICATION NETWORK5 CLAIM FOR PRIORITY

This application claims priority to International  
Application No. PCT/DE00/03328 which was filed in the  
German language on September 25, 2000.

10 TECHNICAL FIELD OF THE INVENTION

The present invention relates to a method and to a  
device for switching a connection between two  
subscribers of a communication network, e.g. a  
telephone network, and in particular, for switching a  
15 connection from an exchange of the communication  
network, ~~after a request coming from a position outside~~  
~~this communication network, for example from the~~  
~~Internet,~~ using the existing switching functions and  
signal transmission functions of the communication  
20 network.

BACKGROUND OF THE INVENTION

A ~~It is known to initiate a~~ connection between two  
subscribers of a communication network can be initiated  
25 by the two subscribers being called separately in each  
case from a special terminal located outside the  
communication network, using a computer as automatic  
operator. As soon as a connection exists to both  
subscribers and the special terminal, the information  
30 signals and the control signals for service indicators,  
if any, are then transmitted by this terminal from one  
connection to the other and conversely. Such a  
switching method is used in telephone networks in call  
centers. The disadvantageous factor is the relatively  
35 complex implementation and the necessary capacity for  
high performance required from the special terminal.

Such switching of a connection in telephone networks is  
of particular interest for the function of "click to

dial" out of the Internet. "Click to dial" is an offer in the Internet in which a user of the Internet is provided with the possibility of setting up a connection directly by instruction between two subscriber numbers of the telephone network, the telephone numbers of which are input or retrieved from a database. Both lines involved must be dialed for this and connected to one another. In most cases, one subscriber is the Internet user himself.

If this function is implemented similar to the call switching in call centers, a controller operating as terminal of the communication network ~~must initiate~~ initiates two connections via the communication network ~~here, too,~~ and, as soon as both connections exist, the controller must ~~forward~~ forwards the information data, ~~that is to say. That is,~~ the digitized voice or other data to be transmitted, of one connection via the other one and conversely. To maintain the features offered by the communication system used in the communication network, e.g. the service indicators of the ISDN in the telephone network, for both subscribers of the initially different connections, ~~these, too,~~ must be transferred from one connection to the second one and adapted, if necessary. This creates considerable expenditure since the computer receives the service indicators like a terminal and forwards them again to the second corresponding connection like a terminal. Additional computing effort is produced by the fact that some data have to be converted and adapted. In the ISDN, for example, it is possible to indicate the telephone number of the other subscriber by means of the CLIP feature. Since there are two connections from the point of view of the communication network, the second call must receive from the controller the indicator of the telephone number of the first call instead of that belonging to the controller, in order to guarantee this feature.

- 3 -

It is also desirable to have a capability of integrating the "click to dial" service with the simplest possible means also in existing network nodes in the case where a network operator itself offers this service.

Figure 1 shows in accordance with the prior art the switching of a connection in a communication network by a computer connected to the communication network as terminal which is used as automatic operator 9. The communication network includes transit exchanges 3 and some access exchanges 4. An exchange center can have both functions and can be both transit exchange 3 and access exchange 4. The transit exchanges are connected to one another by means of transmission links which have at least one information channel 5 and at least one separate signaling channel 6. Figure 1 shows the connection between a first subscriber 7 and a second subscriber 8 by the automatic operator 9. The automatic operator 9 first dials both subscribers 7, 8 in two separate connections via two terminal lines 14. In the example shown, both connections initially take the same path. From the access exchange 4 of the automatic operator 9, they first reach the same transit exchange 3. Depending on the subscriber 7, 8 dialed, the connections can also take separate paths through the communication network after the access exchange 4 to which the automatic operator 9 is connected. In the transit exchange 3, the two connections are switched through completely independently as two different ones. This happens by the information channels 5 and signaling channels 6 being conducted via line trunk groups 2 in the transit exchange 3 and being switched through in a switching network 1 according to the control signals in the signaling channels 6.

If the two connections to the first subscriber 7 and second subscriber 8 have been established, the automatic operator 9 connects the two connections.

## SUMMARY OF THE INVENTION

In one embodiment of the invention, there is a method for switching The invention is, therefore, based on the object of providing a method and a device by means of which it is possible without elaborate adaptations of the transit exchanges and the modules and facilities used in them to establish a connection between two subscribers of a communication network with a common signaling channel which is independent of the information channels and with transit exchanges having at least one switching occurring network and associated line trunk groups, the switching being effected after a request from outside of the communication network. The method includes, for example, connecting two inputs for transmission links at a transit exchange by a data line and permanently allocating at least one pair of information channels. transmitting a control signal on the common signaling channel such that a connection to the first subscriber is switched through from one information channel of the information channels in each case allocated to one another, and a connection is switched through to the second subscriber from the second information channel of the information channels allocated to one another, and forwarding a terminal signaling of the connection to the first subscriber to the connection to the second subscriber via the common signaling channel, and forwarding a terminal signaling of the connection to the second subscriber to the connection to the first subscriber via the common signaling channel.

In another aspect of the invention, the signaling on the common signaling channel is in accordance with the ITU-T signaling system No. 7.

In another aspect of the invention, the signaling messages of an ISDN User Part (ISUP) are transmitted from the first connection to the second connection and from the second connection to the first connection via the ITU-T signaling system No. 7.

In yet another aspect of the invention, PCM30

transmission links are used as inputs.

In another aspect of the invention, PCM24 transmission links are used as inputs.

In another aspect of the invention, the control signal is transmitted via an existing controller of the transit exchange.

In still another aspect of the invention, a connection after a request from another communication network is initiated by a program installed on a network server which is connected to the other communication network.

In another aspect of the invention, the other communication network is the Internet.

In another embodiment of the invention, there is a device in a transit exchange for switching a connection between two subscribers of a communication network with a common signaling channel which is independent of the information channels and with transit exchanges having at least one switching network and associated line trunk groups, the switching occurring after a request from outside of the communication network. The device includes, for example, at least one connection between two inputs for transmission links at the transit exchange by a data line and permanent allocation of at least one pair of information channels, a controller connected to the common signaling channel and which conducts on the common signaling channel a control signal having content that a connection is present on one information channel of the information channels in each case allocated to one another, which connection is switched through to one subscriber, and a connection is present on the second information channel of the information channels allocated to one another, which connection is switched through to the second subscriber, and which forwards the terminal signaling of the connection to the first subscriber to the connection to the second subscriber and from the second subscriber to the first subscriber.

In another aspect of the invention, the controller

uses the signaling protocol according to the ITU-T  
signaling system No. 7.

In another aspect of the invention, the controller transmits the end-to-end signaling messages of the ISDN User Part (ISUP) from one connection to the other connection.

In yet another aspect of the invention, the inputs  
are those for PCM30 transmission links.

In another aspect of the invention, the inputs are  
those for PCM24 transmission links.

In another aspect of the invention, the controller  
is an existing controller of the transit exchange.

In still another aspect of the invention, the transit exchange is a transit exchange of the EWSD system and the inputs are connected by two accesses for PCM lines in each case being connected at one line trunk group.

In another aspect of the invention, the controller  
is a group processor of the line trunk group.

In another aspect of the invention, the controller is connected to a network server which is connected to another communication network to initiate the connection by a program on the network server after a request from the other communication network.

In yet another aspect of the invention, the other  
communication network is the Internet.

### BRIEF DESCRIPTION OF THE DRAWINGS

5 In the text which follows, the invention will be  
explained with reference to the figures in which:

Figure 1 shows the connection of two subscribers by a  
third party according to the prior art, by a computer  
10 as terminal of the network.

Figure 2 shows the connection between two subscribers by a third party by means of the device according to the invention.

Figure 3 shows an embodiment according to the invention of the device in a transit exchange EWSD.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

5 The invention provides a method and a device by means of which it is possible without elaborate adaptations of the transit exchanges and the modules and facilities used in them to establish a connection between two subscribers of the network from one point of the  
10 network after a request from a third party.

~~According to the invention, the object described above is achieved by the features of the independent claims 1 and 9. The dependent claims advantageously develop the~~  
15 ~~basic concept of the invention and provide advantageous embodiments and methods.~~

~~According to the invention, according to claim 1,~~  
20 According to one embodiment of the invention, there is a method for switching a connection between two subscribers in a communication network with a common signaling channel which is independent of the information channels and with transit exchanges  
~~consisting of in each case~~ including at least one  
25 switching network and associated line trunk groups is provided, the switching being effected after the connection has been requested from a third party.

Initially, two inputs for transmission links at a  
30 transit exchange are connected by a data line. This can already been done by means of a signal data line. This also results in a permanent allocation of the information data channels in ~~each case in~~ pairs, for example the voice channels in a telephone network. In  
35 networks operating with a synchronous digital hierarchy or a plesiochronous digital hierarchy on the transmission links or generally in the case of multiplex lines, ~~in each case~~ at least one information channel of one input is permanently allocated to an

information channel of the other input of the transmission link via the corresponding timeslot. Naturally, it is also possible, in an ATM network, to achieve a fixed paired information channel allocation by means of such a hardware connection of the inputs of transmission links by utilizing the coding and decoding methods provided by the network since for each transit exchange a transmission link, which, in turn, is connected to the exchange itself, acts in such a manner as if it were connected to an adjacent transit exchange. Thus, the methods already in existence produce a fixed information channel allocation since an unambiguous defined information channel allocation must also exist between transit exchanges.

15 Furthermore, according to still another embodiment of  
the invention, a control signal is transmitted on the  
common signaling channel, which has the content that a  
connection is present on one information channel of the  
20 information channels in each case permanently allocated  
to one another, which connection ~~must be~~ is switched  
through to the first subscriber and, at the same time,  
that a connection is present on the second information  
channel which must be switched through to the second  
25 subscriber. As a result, from the point of view of the  
communication network, two connections are set up, both  
of which apparently come from the hardware loop, the  
connection between the two inputs.

30 Finally, the incoming terminal signaling of the connection to the first subscriber in one call are forwarded to the connection to the second subscriber via the common signaling channel and conversely.

35 This can be advantageously carried out with relatively little expenditure even at transit exchanges already existing. Since the junction line is not a terminal and thus does not generate its own terminal signaling, the full extent of the features of the protocol used can already

in existence.

According to the invention, a connection can be initiated in a similar manner by a request from another communication network. For this purpose, a program installed on a computer which is connected to ~~this~~ the other communication network issues the instruction for setting up the connection. In particular, the "click to dial" feature can thus be implemented if the other communication network is the Internet.

~~According to claim 9 of the invention~~ In one embodiment, a device in a transit exchange is also provided for switching a connection between two subscribers in a communication network. The communication network exhibits a common signaling channel which is independent of the information channels. Furthermore, this is a communication network with transit exchanges consisting of in each case at least one switching network and associated line trunk groups.

At least one pair of information channels is permanently allocated for information data by at least one connection between two inputs for transmission links at the transit exchange by means of a data line.

Furthermore, the device ~~consists of~~ includes a controller (CTD controller) which is connected to the common signaling channel and which conducts on the common signaling channel a control signal having the content that a connection is present on one information channel of the information channels in each case permanently allocated to one another, which connection ~~must be~~ is switched through to one subscriber, and ~~that~~ a connection is present on the second information channel of the information channels in each case permanently allocated to one another, which connection ~~must be~~ is switched through to the second subscriber.

The controller forwards the terminal signaling of the connection to the first subscriber to the connection to the second subscriber and conversely.

5    ~~Advantageously,~~ a A connection between two subscribers of the communication network can be set up with ~~only~~ little expenditure since it is ~~only~~ the computing effort for generating the signals of the common signaling channel and the transmission of the terminal  
10    signaling by the controller which ~~must be~~ are produced. The transit exchange in the device according to the invention sees itself as an apparent adjacent transit exchange and the synchronization of the information data and the permanent allocation of the information  
15    channels is thus effected with the existing means of the transit exchange.

The device can also advantageously be installed in preexisting transit exchanges.

20    The controller advantageously uses the signaling protocol according to the ITU-T signaling system No. 7.

According to ~~claim 11~~ another aspect, the controller  
25    advantageously transmits the end-to-end signaling messages of the ISDN User Part (ISUP) from one connection to the other one and conversely.

It is also ~~advantageous~~ preferable to provide a data  
30    line between two inputs for PCM30 transmission links.

It is also ~~advantageous~~ preferable to provide a data line between two inputs for PCM24 transmission links. The device can be simplified if the controller (CTD  
35    controller) is an existing controller of the transit exchange.

According to ~~claim 15~~, ~~according to~~ another aspect of the invention, it is ~~advantageous~~ preferable to provide

the device in a transit exchange of the EWSD system. The inputs are then connected by two inputs for PCM lines in each case being connected at one line trunk group (LTG-C).

5

The group processor of the access section of the transit exchange according to the EWSD system can be provided as controller (CTD controller). Advantageously, no external additional controller is then needed since the one existing in the line trunk group has sufficient capacity also to serve as controller of the device proposed here.

The controller can be connected to a computer which, in turn, is connected to another communication network in order to initiate the connection by a program on this computer after a request from the other communication network.

20 The other communication network is advantageously the  
Internet and the "click to dial" feature is implemented  
thereby.

~~In the text which follows, the invention will be~~  
25 ~~explained with reference to figures 1 and 2, in which:~~

~~figure 1 shows in a diagram the connection of two subscribers by a third party according to the prior art, by a computer as terminal of the network.~~

30

~~figure 2 shows in a diagram the connection between two subscribers by a third party by means of the device according to the invention,~~

35 figure 3 shows in a greatly simplified manner an  
embodiment according to the invention of the device in  
a transit exchange EWSD.

~~Figure 1 diagrammatically shows in accordance with the~~

- 13 -

prior art the switching of a connection in a communication network by a computer connected to the communication network as terminal which is used as automatic operator 9. The communication network consists of transit exchanges 3 and some access exchanges 4. An exchange center can have both functions and can be both transit exchange 3 and access exchange 4. The transit exchanges are connected to one another by means of transmission links which have at least one information channel 5 and at least one separate signaling channel 6. Figure 1 shows the connection between a first subscriber 7 and a second subscriber 8 by the automatic operator 9. The automatic operator 9 first dials both subscribers 7, 8 in two separate connections via two terminal lines 14. In the example shown, both connections initially take the same path. From the access exchange 4 of the automatic operator 9, they first reach the same transit exchange 3. Depending on the subscriber 7, 8 dialed, the connections can also take separate paths through the communication network after the access exchange 4 to which the automatic operator 9 is connected. In the transit exchange 3, the two connections are switched through completely independently as two different ones. This happens by the information channels 5 and signaling channels 6 being conducted via line trunk groups 2 in the transit exchange 3 and being switched through in a switching network 1 according to the control signals in the signaling channels 6.

If the two connections to the first subscriber 7 and second subscriber 8 have been established, the automatic operator 9 connects the two connections.

Figure 2, in contrast to Figure 1, shows by way of example the arrangement of a device according to the invention for switching a first subscriber 7 and a second subscriber 8 in an embodiment with request of the connection by a network server 13, for example of

- 14 -

the Internet. The drawing also shows an embodiment in which the device according to the invention is integrated in a transit exchange 3. In a transit exchange 3 ~~consisting of~~ including the main modules

5 switching network 1 and line trunk groups 2, two transmission links are connected by a data line 12 and thus at least two information channels 5 are permanently allocated to one another via the data line 12. The associated signaling channels 6 are connected

10 to a controller (CtD controller - click to dial controller) 10. In the embodiment shown, this controller is one of the controllers already existing in the transit exchange 3 for controlling the transit exchange 3 itself. The controller 10 is connected to a

15 network server 13 via a junction line 11. The network server 13 can then be connected to another communication network, for example the Internet. If the network server 13 then receives a request for setting up a connection between the first subscriber 7 and the

20 second subscriber 8, it issues the instruction for this via the junction line 11 to the controller 10. The controller 10 then conducts a control signal to the signaling channel 6 that a connection is present on the information channel 5 connected to the data line 12

25 which is to be switched through to the first subscriber 7 and which, lastly, is connected via the switching network 1 to the first subscriber. Similarly, a connection is switched from the data line 12 to the second subscriber 8 via the switching network 1 by

30 means of a corresponding control signal on the signaling channel 6. Since the transit exchange 3 sees itself as an adjacent transit exchange via the information channels 5 and the data line 12, the information channels 5 are permanently allocated to one

35 another via the synchronizing devices and methods normally existing between the transit exchanges and transmit the information data. The controller 10 also transmits, on the signaling channel 6, terminal signaling messages coming from the connection to the

- 15 -

first subscriber 7 to the connection to the second subscriber 8 and conversely.

Compared with the prior art, the embodiment of the device according to the invention described has the advantage that it can be set up with little expenditure and also subsequently in an existing transit exchange 3. It is only necessary to install the data line 12, to supplement an existing controller by software adaptation to the controller 10 and to set up an interface as junction line 11 to a network server 13. This can also be done by utilizing existing system interfaces to the outside.

Figure 3 shows in a simplified manner a further embodiment according to the invention of the device described above in a transit exchange of the EWSD type.

A transit exchange of the EWSD type consists of a switching network 1 (SN) and at least one line trunk group 2 (LTG). In this case, four are shown, one of which is drawn enlarged and with its modules. The switching network 1 has, for the control function, its own controller, the switch group control 15 (SGC). A line trunk group 2 is built up of line trunk units 17 (DIU,LTU), a group switch 19 and a line interface unit 20. If the line trunk group 2 is designed for PCM30 transmission links as in the embodiment shown, the line trunk group 2 has four line trunk units 17. Each line trunk unit 17 provides a PCM30 access 22 for a transmission link. In each case two of the PCM30 accesses 22 are connected to one another by data lines 12. The group processor 21 is at the same time the signal processor 10. The line trunk units 17 combine the information channels in a group switch 19 (GS). Four 2-MBit PCM lines of 32 information channels each are combined in the group switch 19 to form an 8-MBit line with 128 channels which are forwarded to the switching network 1 via the interface of the line

- 16 -

interface unit 20. The connection is set up as already described above. Since the group processor 21 is connected to the processor of the switching network 1, the switch group control 15 and the central processor 5 16 via internal interfaces, it can be used as controller 10. The software must be appropriately adapted. The instruction for setting up a connection to the controller 10 can also be transmitted via these interfaces. Using the embodiment described, it is, 10 therefore, possible to establish the device according to the invention by means of two data lines 12 and a software supplement. In particular, subsequent installation in existing transit exchanges EWSD which are used in large numbers is also conceivable.
